

ORGANIC CHEMISTRY CRACK NOTES

MOLECULAR STRUCTURE

Hybridization:

an atom is **SP³** hybridized if it contains only single bonds (tetrahedral geometry) 109.5°

an atom is **SP²** hybridized if it contains 1 double bond (trigonal geometry) 120°

an atom is **SP** hybridized if it contains 2 double bonds or 1 triple bond (linear, 180°)

NOTE this only works for neutral atoms a carbocation is sp² hybridized

Determining formal charge: # of electrons an atom wants (4 for C, 5 for N, 6 for O) – (# of bonds and each electron in a lone pair)

a single bond has 1 σ bond

a double bond has 1 σ bond and 1 π bond

a triple bond has 1 σ bond and 2 π bonds

Resonance:

- occurs when there's α,β-unsaturation next to an atom with a charge or an atom with a lone pair next to a carbocation

- to draw the resonance contributor always move electrons (ie. Either the double bond in the case of a cation and lone pair of electrons in the case of a negative charge)

Naming alkenes: E or Z

When an alkene is tri- or tetra- substituted, E/Z nomenclature is used. To do this, each substituent across the double bond is assigned a priority according to the Cahn-Ingold-Prelog rules:

- Rank according to atomic number of attached atom (Br > Cl > O > N > C > H)
- If the above rule does not solve the ranking, look at 2nd, 3rd, 4th, atoms away to try and find a difference in atomic number
- Multiple-bonded atoms are equivalent to the same number of single-bonded

Assigning stereochemistry to chiral centers:

→ substituents are ranked according to the Cahn-Ingold-Prelog rules (E/Z alkenes)

Once substituents have been ranked, the lowest ranked is aimed away from the viewer (i.e. into the page).

- If the remaining 1st, 2nd and 3rd ranked substituents are arranged:

- Clockwise:
- Counter-clockwise

R Stereochemistry
S Stereochemistry

Racemic mixtures:

equal (50:50) mixtures of two enantiomers; often denoted by (+/-)

Enantiomers have identical physical properties but diastereomers do not.

Meso compounds- molecules that have at least 2 stereocentres BUT are achiral

because they have a plane of symmetry.

Fischer Projections:

- most highly oxidized group at the top (position A)

- longest carbon chain is vertical (A to C)

- Can rotate 180° but not 90 or 270°

- Can hold one substituent in place then rotate others either clockwise or counter-c.w.

ORGANIC CHEMISTRY CRACK NOTES

Important functional groups:

alkane

alkene

alkyne

alcohol

ether

amine

aldehyde

ketone

carboxylic acid

ester

amide

Acidity Summary:

HYDROCARBONS, ALCOHOLS, AND SUBSTITUTIONS/ELIMINATIONS

Cyclohexane:

Ring-flip in cyclohexane

1,3-Diaxial interactions (occur between A-C, C-D and A-D, on the left above)

- Result from steric strain between axial substituents 3 carbons apart on a ring
- Equatorial position generally preferred to avoid 1,3-diaxial interactions

Radical Reactions:

→ Homolytic bond breaking

An example of a radical reaction mechanism

Alkenes

Alkenes may be synthesized via alcohol dehydration

or dehydrohalogenation (similar mechanism).

Addition reactions:

Halohydrin

Hydration: Industrial

Hydration: Oxymercuration

Hydration: Hydroboration

Ozonolysis

Permanganate Cleavage

Substitution/Elimination Summary:

S_N^2 $1^\circ > \text{benzylic/allylic} > 2^\circ > (3^\circ \text{ does not work})$
 Needs a strong nucleophile

ORGANIC CHEMISTRY CRACK NOTES

SN¹ 3° > benzylic/allylic > 2° > (1° does not work)
Weak nucleophiles will do since any nucleophile will attack a carbocation

E² Doesn't matter what the carbon with the nucleophile is since you're pulling an H
Need a strong base

E¹ 3° > benzylic/allylic > 2° > (1° does not work)
Weak bases will do since any base will attack a carbocation

Carbocation Stability: 3° > benzylic/allylic > 2° > 1° > methyl

When the atom with the lone pair can act as a base or nucleophile:
SN² and E² will compete and SN¹ and E¹ will compete.

To determine the mechanism:

- Look at degree of substitution of the halide, the more substituted, the greater the chance that it will undergo an SN¹ or an E¹

- Look at what the halide is reacting with:

- a Nucleophile (SN² or SN¹)

- a Base (E² or E¹)

- If you have a molecule which can act as a base or a nucleophile look at the double bond

that would be formed in the elimination mechanism. If it is conjugated or highly substituted elimination will be favoured over substitution.

• **Nucleophiles:** are atoms with a lone pair of electrons. In nucleophilic substitution they donate the pair of electrons to form a new covalent bond.

(factors listed from most important to least important)

I⁻ > Br⁻ > Cl⁻ > F⁻

CN⁻ > OH⁻ > F⁻

H₂S > H₂O

- the best nucleophiles are **negatively charged** (ie. OH⁻ > H₂O)

- the **larger the atom** the better the nucleophile (ie. I⁻ > Br⁻ > Cl⁻ > F⁻)

- **smaller molecules** are better nucleophiles than larger ones

- the lower electronegativity of the atom with the lone pair, the stronger the Nu (ie. CN⁻ > OH⁻ > F⁻)

• **Leaving Groups:** groups that best stabilize a negative charge (tosylate, iodide, bromide, chloride, acetate)

(factors listed from most important to least important)

- good leaving groups leave **neutral**

- good leaving groups are **stable anions** (resonance stabilized)

- **larger** the atom bearing the negative charge the better the Lv group (I⁻ > Br⁻ > Cl⁻ > F⁻)

- more **electronegative** the atom bearing the negative charge the better the leaving group (F⁻ > O⁻ > N⁻ > C⁻)

Note: halogens are good leaving groups too as they are very electronegative, but they don't have resonance stabilization like tosyl groups

• **Bases:** Are atoms with a lone pair of electrons. An atom with a lone pair of electrons can be a base or a nucleophile. By definition if an atom with a lone pair attacks at the carbon it is a nucleophile. If it pulls a proton it is a base.

- good bases are **negatively charged**

- the **bigger** the molecule with the lone pair the better the base and poorer the Nu

Nucleophile

small	→	Nu
large	→	base
negative	→	strong
neutral	→	weak

Grignards:

ORGANIC CHEMISTRY CRACK NOTES

A Grignard will act as a base 1st if there's an acidic proton around (ROH, SH, RCO₂H) otherwise it acts as a Nucleophile.

Is it an Oxidation or Reduction?

- oxidation is a gain of oxygen or loss of hydrogen

- reduction is gain of hydrogen or loss of oxygen

NOTE treat S, I, Br, Cl and OH groups as oxygen

NOTE addition of HI, HBr, HCl or H-OH is **not** an oxidation or reduction since

you're adding an O and an H

Alcohols

Alkyl Halides from Alcohols

Pinacol rearrangement

Tosylation

Epoxide Formation

Alkyl halide formation from ether

Oxidations:

Reductions:

CARBONYLS AND AMINES

Carbonyl reactions:

Nucleophilic addition reactions

These reactions produce an alcohol. Nucleophiles include H₂O, CN⁻ or RMgX

Wittig Reaction

Conjugate addition

ORGANIC CHEMISTRY CRACK NOTES

The aldol condensation between two aldehydes to give a β -hydroxy aldehyde

Claisen condensation is similar to the aldol reaction, with esters as the starting material

Michael Addition

Carboxylic Acid

Amines

Basicity Review

A base is an atom with a lone pair of electrons. The best bases are negatively charged.

Reductive Aminolysis

Hoffmann Elimination:

Diazotization Reaction:

Diazonium Coupling Reaction:

ORGANIC CHEMISTRY CRACK NOTES

BIOCHEMISTRY AND LAB TECHNIQUES

Lipids: hydrolysis

Amino Acids:

Carbohydrates

The human body can assimilate only D-fructose and D-glucose and cannot assimilate L-fructose and L-glucose.

An Approach To Structure Determination:

- Determine the units of unsaturation
- Gather information from the IR spectrum
From an IR spectrum you should be able to tell if there is a $\text{C}=\text{O}$, $\text{O}-\text{H}$, CO_2H , $\text{N}-\text{H}$, nitrile, $\text{C}=\text{C}$ or alkyne
 - an IR is good for determining functional groups present when there are heteroatoms in the molecular formula
 - ex. If there is an O in the molecular formula the IR can tell you if it is a ketone or aldehyde, carboxylic acid or alcohol. If none of these peaks are observed then it is probably an ether
 - ex. If there is an N in the molecular formula the IR can tell you if it is an $\text{N}-\text{H}$ or nitrile. If neither of these peaks are observed the N may be a tertiary amine or amide. If it was an amide you would observe a $\text{C}=\text{O}$ peak in the IR.
- Gather information from the NMR spectrum
 - Easy things to spot in the NMR are aromatic ring, aldehyde, carboxylic acid and alkene.
 - If there is 4 or more units of unsaturation immediately look to see if there is an aromatic ring in the structure (peak in the NMR spectrum between 6.8-8 ppm)

- Then look for the number of CH_3 peaks there are (integrate for 3 protons)
- Then use all the data you've learned from the molecular formula, IR and NMR to draw possible structures. Then look at each structure and compare them to the number of chemical shifts in the NMR and the splitting and integration observed in the NMR. The structure should match the observed NMR data perfectly. If it doesn't it is not the correct structure. Eliminate it and look at the next possible structure.
